The Impact of Russia-Ukraine conflict on Global Commodity Brent Crude prices

HEMENDRA PAL

ALTREICH THINKTANK, 15/08/2023

Abstract

using World Bank time series data. The conflict's seeking to navigate the complex landscape of comized by intricate supply and demand dynamics, is stability. analyzed through advanced time series techniques and machine learning modeling. Univariate models such as AutoCorrelation Function (ACF) and Partial AutoCorrelation Function (PACF) are employed to discern temporal patterns in Brent Crude prices. Additionally, Seasonal Autoregressive Integrated Moving Average (SARIMA) and Exponential Smoothing State Space (ETS) models are utilized to capture complex seasonality and trends in 1 the data.

Moving beyond traditional methods, multivari- 2 ate models are leveraged to comprehensively grasp the multifaceted impact of the conflict. Principal ³ Component Analysis (PCA) and Factor Analysis are applied to uncover latent variables influencing Brent Crude pricing in the context of global trade disruptions, inflation, and diplomatic negotiations. These extracted components are then integrated with ensemble machine learning algorithms, including Random Forest, Extra Tree Classifier, Gradient Boosting, K-Nearest Neighbors, and Decision Trees. The fusion of multivariate time series analysis and machine learning empowers a holistic understanding of the conflict's intricate repercussions on commodity prices.

The analysis reveals that not only direct factors related to geopolitical tensions but also indirect economic data is crucial in determining Brent Crude prices. Factors such as declining industrial demand for precious metals like silver, disruptions in vehicle production due to supply chain breakdowns, reduced demand for automotive autocatalysts, weak copper demand from China, and unexpected changes in steel consumption have contributed to the observed fluctuations in Brent Crude prices.

Through a comprehensive exploration of time se- 6 ries data and advanced machine learning modeling,

this research contributes to a a clearer understanding of the complex connections between the crisis in Russia and Ukraine and the price of commodi-This study investigates the impact of the Russia- ties globally. ⁴ 1 Introduction

⁴ In today's interconnected global economy, understanding the intricate relationship between geopolitical events and commodity prices has become more crucial than ever. The ongoing conflict between Russia and Ukraine has emerged as a poignant example of how geopolitical tensions can reverberate across financial markets, impacting vital commodities such as Brent Crude oil. This 7 study delves into the multifaceted dynamics at play, utilizing a blend of traditional time series analysis 8 and advanced machine learning techniques to unravel the impact of the Russia-Ukraine conflict on Brent Crude commodity prices.

The Russia-Ukraine war has unleashed a wave of disruptions that have rippled through supply chains and caused seismic shifts in the energy sec- tor. Notably, Brent Crude prices, a key benchmark for global oil markets, have been significantly affected. The fallout encompasses a spectrum of factors including supply chain bottlenecks, production delays, amplified market uncertainty, and economic turbulence within major oil producing and consum-8 ing nations.

To comprehensively explore the intricate inter-9 play of these factors, this study harnesses a suite of technical tools. Concepts like AutoCorrelation 9 Function (ACF), Partial AutoCorrelation Function (PACF), Seasonal Autoregressive Integrated Movsect the underlying time series data. Discussion Research and Questions

4.1Impact of the Russia-Ukraine War:

The Impact of Ukraine Russia War has been some considerable advantages to Oil and Gas producing countries like Russia and Saudi Arabia, who have used the war situation for price manipulations, however, the war has also exposed these countries to global risks caused due to supply chain disruptions[32]. For oil-consuming countries like India and Ghana, the war has led to increased energy prices and scare of increased inflation. In many countries, these economic situations have led to government intervention and policy measures. [20][31] Top Oil and Gas companies such as Exxon and Chevron have seen a drop in their earnings, and subsequently the Brent Crude has reached a level of USD 75 / Barrel after hitting the USD 100 / Barrel, after the onset of the war on 24 February 2022. The overall profitability as well as the decision making in the Oil and Gas Industry has been affected by the war. [35]. As per a Journal Article in Journal of Energy and Social Sciences Research, Nigeria might take advantage of higher oil prices through its oil exports. Hence, the war might be advantageous for Nigeria's economic growth and revenues from oil exports. [22] As per Wood Mackenzie a Global Consulting Firm, The war has changed the market in five ways [8] firstly, the risks of geopolitical tensions has increased leading to disruptions in global supply of oil, secondly, the rise in oil and gas prices has changed the consumer spending patterns as well as increased inflation rates. thirdly, the energy diversification and renewable energy efforts to all time high, Finally, the scrutiny on projects with more environmental impact has been on all time high. As per another article from The Times, amidst increased geopolitical tensions, Saudi Ara-- Ensemble machine learning algorithms: bia threatened to decrease it production output, commodity (ETC) has led to increased volatility. [3][4] Oil Marketing Companies (OMC's) have been subjected to greater oil uncertainty crude pains af-- Analysis: The study utilizes World Bank time ter the war due to increased volatility, increased plies. Russian marthe risks associated with the war.

4.2Supply Chain Disruptions:

The supply and demand uncertainty, increased volatility and prices have led to elevated challenges to the consumers and corporate companies, (Renewable Energy, 2023). The Price Volatility producers and consumers have been affected. has been further worsened due to Saudi Arabia's continued threats on cutting oil production levels. (Times, 2022). The reduction in supply by Russia, after the record number of sanctions has resulted The geopolitical tensions and conflicts lead to in market imbalance and supply shortages, thereby increasing the prices. Saudi Arabia's decision to extend production cuts just exacerbated the oil market woes (ABC News, 2023). As per Wood Mackenzie(2022), the war has triggered a domino affect resulting in disruption in logistics, transportation and infrastructure, Oil production, transportation Russia. The war has caused a potential unrest in and refining have resulted in market fluctuations. the minds of traders, because of the concerns over ETFS (The world's largest ETF), has seen record oil supply disruptions and the impact on the trade outflows after the war (ETF Stream 2022), hence there is a clear shift in the investor's sentiment, after the war. Oil consuming economies of Ghana and India have faced higher oil prices in their imports, leading to an increase in the price and sustained inflationary pressures. [The Conversation, 2022] Thus Supply Chain Disruptions post war have resulted in increased volatility, supply shortages and imbalance between Supply and demand, causing an impact on international relations, global geopolitics and overall global economy.

Production Delays: 4.3

fluctuations have become a global phenomena, for build on their stockpile of inventories to absorb the the oil producing countries. Investments and Earnings of Oil Producing comthe earnings have affected company's performance. panies has reduced and due to price hike both the

Market Uncertainty: 4.4

disruption of the market and enhanced market uncertainties, leading to less confidence in the market and the investors taking their investments off the market. Apart from the unanimous sanctions, the onset of war led to more than 1000 multinational companies to pack their bags and investments from routes. More and more companies are adjusting their trading strategies to absorb these market uncertainties and pricing volatility.

In the international market dynamics all these factors lead to increase in the prices of the Brent Crude Oil. To mitigate the risks and market uncertainties due to the volatility in Brent crude prices, some nations such as the UK and the US, have put a price cap and embargoes on Russian Oil products.[33][38] Although, the market pundits and economists debate such market moves, however, it is a measure to absorb some uneasiness from the mind of consumers. After the start of the Ukraine Production delays, supply disruptions and price - Russia war, like any other war, countries tend to the Brent Oil Prices.

4.5**Options for Russia and Euro**pean Nations:

Although the ongoing Russia-Ukraine conflict had a far reaching affects globally. Russia and European nations have several options, some of the mitigating strategies include, diversification and investments in renewable energy sources, implementing price caps, and increasing the domestic production. Both Russia and EU should have less reliance on Russian Conventional Energy resources, and the diversification of portfolio should be achieved by investing in alternative energy such as renewable energy, nuclear power, and liquefied natural gas (LNG). The diversification would in-turn decrease the vulnerability of the EU by not relying on Russian Oil and Gas Supplies and would help stabilize the global prices of Brent crude prices.[10] European nations can enhance their domestic production. This strategy entails investments in exploration and research development. improving extraction techniques, and incentivizing the domestic production, for less supply uncertainties due to Russian imports. European Nations and the US have announced price caps to protect the markets from excessive price increases. [38][41] This kind of policy is made to prevent stockpiling of inventory, and reduce the risks of price fluctuation subjected to the market uncertainties and risks. Investing in renewable energy such as wind, solar, biogas, hydro can help the reliance of conventional energy resources including Russian Oil and Gas. Similarly, market subsidies to the new and old users, tax incentives and reg- Diversification of renewable energy which is mostly ulatory framework that supports renewable energy plans will create a more stable political environment for both Russia and the EU. International Cooperation can also help in mitigating the impact ing reliance on conventional resources specifically of Russia Ukraine War and it's affect on the Brent Crude Oil prices.

4.6**Diplomatic Negotiations:**

Diplomatic negotiations continue to play a crucial more options for domestic production, promoting role in stabilizing the uncertainties in the crude oil energy efficiency and alternative suppliers can help market caused due to Russia- Ukraine War. Diplo- in lesser reliance on Russian Oil and Gas. However, matic negotiation on production levels, price con- these options are mostly relevant for EU Countrols, international relations and while keeping the tries, Ukraine, the US and the UK. Pro- times after the war. [44] There are significant ecoduction Levels or Production Cuts / Restrictions nomic opportunities, generate green jobs, attract can lead to stability in the Brent crude oil mar- investments in green energy, green technologies, and

kets. Diplomatic negotiations between the UK, the coalition countries and the US, led to a price cap and embargoes on the Russian Oil Products. This move was done to prevent the consumers from excessive price increases and market shocks due to this price increase. Measures such as Price Cap is meant to restore confidence of the people in their government. Even after the sanctions on Russian companies and closures of foreign businesses in Russia especially Moscow region where more than 500 companies were closed, was possible only through negotiations. Diplomatic negotiations help to ease tensions, facilitate dialogue and open the doors towards peaceful resolution. Improved international relations even after the war helps to regain the trade and market stability after the end of war. Cooperation between the oil producing, oil consuming, oil trading stakeholders is of extreme importance for collaboration, cooperation and communication for finding a peaceful solution for easing of geopolitical conflict and towards a more stable environment. These negotiations can help in stabilizing the Brent Crude Market and can help to minimize the damages caused due to extreme uncertainties and vagaries of the global oil market. Thus, agreements on production levels, price control, stakeholder engagement, International cooperation and International relations are all important for not-only keeping Brent crude prices under check but also for finding a long term peaceful solution to the conflict.

4.7 Diversification of Energy / Investment in Renewable:

domestically produced and not subjected to geopolitical tensions and vagaries / uncertainties of the global market can be a good option for reduc-Russian Oil, and thus mitigate the disruptions caused due to sanctions, restrictions and embargoes on Russian Oil Products. A shift towards solar, wind, hydro, geothermal can mean less reliance on imported oil and gas. lows: ARIMA Model for 6 Brent Original Time Series = Trend + Seasonality + ErrorCrude Price forecast generation

For the purpose of forecasting time series, the ARIMA (Autoregressive Integrated Moving Aver- 1. Trend (Td_tt) : The underlying pattern or longage) is a frequently employed statistical modeling term movement in the data. technique. It combines autoregressive (AR), differencing (I), and moving average (MA) components occurs at regular intervals. to capture the different patterns and trends present in the data.

The AR component of the model captures the relationship between the variable and its own lagged values. It represents how the variable's current value is linearly related to its past values. The AR component is denoted by the parameter p, denoted by the number of included lagged terms.

The differencing component (I) is the integer representing the number of times the time series is differenced to achieve stationarity, for removing the trend and seasonality from the series. Stationarity is important for forecasting because many time series models assume the series to be stationary. The differencing component is denoted by the parameter d, which determines the order of differencing required to make the series stationary.

tween the variable and its past forecast errors. It tual dataset represents how the variable's current value linearly

Components

2. Seasonality $(Sy_t t)$: The repeating pattern that

3. Error or Residual $(Er_t t)$: The random fluctuations that cannot be explained by the trend and seasonality.

The MA component captures the relationship be-Figure 4: ARIMA Decomposition performed on ac-

472

The Seasonal data is separated into Residual, Trend, Error and Seasonality, that's the reason that such kind of seasonal data decomposition is called as ETS Decomposition. Since, from the decomposition of data, it is clear that our data is not stationary, hence, Auto Regressive Integrated Moving Averages is a better technique for doing forecasting of this time series data. Generally, for government policy decisions, either the classicial, regression, exponential smoothing or Box Jenkins method of ARIMA Forecasting Modeling is used.

ARIMA **Decomposition:** 7 **Error-Trend-Seasonality**

9 Mathematical Representation

Mathematically ARIMA decomposition can be represented as follows:

$$y(t) = T(t) + S(t) + Er(t)$$

Where:

y(t): is the observed time series at time t

T(t): is the trend component at time t

S(t): is the seasonal component at time t

Er(t): is the residual component at time t

tive components can be represented as:

$$y(t) = T(t) \cdot S(t) \cdot Er(t)$$

10ARIMA Model

The ARIMA(p,d,q) model can be represented mathematically as:

$$(1-\phi_1B-\phi_2B^2-\ldots-\phi_pB^p)(1-B)^dX(t)$$
equals

 $(1 + \theta_1 B + \theta_2 B^2 + \ldots + \theta_q B^q) \epsilon_t$ where: - X(t) is the time series

- B is the backshift operator, which shifts the time series by one lag $(BX_t = X_{t-1})$

- ϵ_t is white noise

- p is the order of the autoregressive part of the Python: model

- d is the degree of differencing (integer representing the number of times the time series is differenced to achieve stationarity)

- q is the order of the moving average part of the model

- $\phi_1, \phi_2, \ldots, \phi_p$ are the autoregressive coefficients - $\theta_1, \theta_2, \ldots, \theta_q$ are the moving average coefficients

Figure 5: Forecast - Classical Forecasting Model

Figure 6: Forecast based on ETS modeling.

Correlation Heatmap 11

In some instances, rather than being multiplicative, A correlation heatmap is a graphical representation trend and seasonality could be additive. The addi- of the correlation coefficients between different variables in a data set. It provides a visual summary of the relationships between variables, helping to identify patterns or dependencies.

> Correlation is interpreted as a measure of linear association derived from covariance. Covariance is the strength of linear association between two numerical variables. Thus we can derive correlation from covariance as

$$\operatorname{corr}(x, y) = \frac{\operatorname{cov}(x, y)}{S_x S_y}$$

where $S_x S_y$ is the product of standard deviations. Properties of Correlation to remember -

1. Measures the strength of linear association.

2. It is always between -1 and +1: $-1 \leq \operatorname{corr}(x, y) \leq$ +1

3. It does not have any units

Here is the correlation heatmap generated using

12Engineering, Feature Model Selection. Model Training and Validation, Analysis

Our raw dataset has more than 50 features or commodity products, the raw dataset contains monthly pricing data on each feature from year 1960 to current month. Hence, by doing feature engineering we have done the process of selecting, manipulating and transforming raw data for our machine learning modeling. Since, we are interested in finding the reasons for the change in prices of crude-oil, hence, crude-avg variable is our output variable and the rest of the variables can be considered as input variables. In our feature engineering exercise we have mainly performed

Figure 7: Correlation Heatmap

operations around imputation, replacing values. removal of missing values, scaling, standardization, normalization etc. By doing these feature engineering tasks we have achieved two goals in our research, mainly -

1. Preparing the dataset for doing our machine learning exercise, hence we have achieved compatiblity of our dataset with the chosen machine learning algorithms.

By comparing the machine learning model 2.performance on our data we have achieved a benchmark of machine learning models and pathways to improve the machine learning models performance.

80 percent of their time in massaging the data for data preparation and analysis. Data is the new oil percent , iron ore spot - 14.38 percent and money of 21st Century AI Age.

The mathematical representation of Root Mean 13.4 Square Error (RMSE) in Machine Learning is given by:

$$RMSE = \sqrt{\frac{1}{N} \sum_{i=1}^{N} (y_i - \hat{y}_i)^2}$$

where N is the number of samples, y_i is the true percent, iron ore spot - 9.82 percent. value of the target variable, and \hat{y}_i is the predicted value of the target variable.

The mathematical representation of Accuracy in 14Machine Learning is given by:

$$Accuracy = \frac{\text{Number of correct predictions}}{\text{Total number of predictions}} \times 100$$

where the number of correct predictions is the count of correctly predicted samples, and the total number of predictions is the count of all samples.

13Analyzed **Scenarios** for **Feature Engineering**

Adaboost Regressor 13.1

This feature engineering exercise yielded Platinum, Iron Ore Spot and Silver as top three features. The prediction accuracy was 93.28 percent, MAE was 6.61 and R Squared Value was 94.54 percent. The top three features selected by our machine learning model are- platinum - 34.83 percent, silver - 24.17 percent and iron-ore-spot -11.32 percent.

13.2Extra Tree Regressor

This feature engineering exercise yielded Platinum, Iron Ore Spot, Copper, Gold and Silver as top The prediction accuracy was 98.33 features. percent, MAE was 2.23276 and R Squared Value was 99.07 percent. The top features selected by our machine learning model are - iron ore spot -17.96 percent, platinum - 16.01 percent, copper -15.24 percent , silver - 10.75 percent and gold -10.69 percent

This feature engineering exercise yielded Platinum, Iron Ore Spot 95.47 percent accuracy as top As per Forbes Survey, Data Scientists spend features. The top two features selected by our machine learning model are - platinum - 74.88

Random Forest

This feature engineering exercise yielded Platinum, Silver and Iron Ore Spot as top features. The prediction accuracy was 97.29 percent, MAE was 2.8794 and R Squared Value was 97.49 percent. The top features selected by our machine learning model are - platinum - 38.19 percent, silver - 35.01

Key Inferences from Factor Analysis

Explanation of Brent Crude price spike with these features -

Figure 8: Scenario 1 - Adaboost Algorithm

Figure 9: Scenario 2 - Extra Tree Algorithm

Figure 10: Scenario 3 - Decision Tree Algorithm

Figure 11: Scenario 4 - Random Forest Algorithm

Silver

- Silver prices slumped due to waning industrial demand

- More than 50 percent of the Silver yearly consumption is driven by industrial demand.

- Silver is used in electronics , solar panels and photographic equipment.

- Consumer Electronic output was lowest in November 2022.

- China's Purchasing Manager Index was lowest in April 2022, while USA's PMI rating took a deep plunge in June 2022.

- Investment Demand of Silver Fell Sharply, which is the second highest demand of silver after industrial applications.

Platinum

- Palladium and Platinum are widely used in Automotive Industry.

- The war has hit the vehicle production which was already reeling due to disruption of supply chains during COVID-19 and although the Russia's Norlisk Nickel which is the largest producer of palladium did not let the Ukraine-Russia war to disrupt it's production and delivery of palladium. European car makers have been hit due to the shortage of wiring harness supply from Ukraine, It's due to the war.

- Decline in the demand of the Autocatalyst in the Auto Industry has led to downward pressure on palladium and platinum prices.

- Platinum's use in electrolyzers, carbon free hydrogen, production and fuel cells.

Copper

- The decline in Copper prices due to weak demand from China since the April 2022.

- China accounts for approximately 57 percent of Global Copper Consumption.

- Copper is consumed in Electric Vehicles, renewable power and associated electric grid infrastructure.

Iron Ore

- Iron ore imports have been under a lot of pressure in China, due to lower than expected steel consumption. Iron ore purchases in China slumped to 10 month low in April.

- Chinese Officials are considering an official cut by 2.5 percent to the steel production output in the year 2023.

- Experts say that peak Iron Ore demand in China has already been reached in the year 2020.

- Market Pundits consider the price of iron ore and crude oil maintain a complex relationship, movement and precious metals and minerals.

Gold

- The Prices of Gold follow the trends in Oil A comparison of Purchasing Manager Index Prices. Generally, Oil exporting countries hedge their risks in Oil by buying more gold from the revenues generated from the Oil exports. [54]

most parts of the world, and rising oil prices lead Copper and Iron Ore are all used in Industrial Apto inflation but investments in gold are considered as a counter for rising inflation.

- Oil prices can be used non-linearly to predict the gold prices but not vice versa. [54]

- The work on relationship between oil prices and gold prices is however limited. [54]

Drivers of Brent Crude Oil Prices -

1. Disruption in Oil Supplies from Russia.

2.Steep rise in Inflation in North America after the onset of war and throughout Year 2022.

Strong exchange rate of USD, compared 3. to other currencies.

Market Volatility, Drop in demand of Pre-4 cious Metals, Iron Ore, Copper and overall Weak industrial and economic activity,

5.Record Number of Sanctions against Russia by Global Companies.

Our four features namely Platinum, Silver, Iron Ore Spot and Copper account for the best accuracy in our prediction results.

Figure 12: Plot of PMI Index

hence our machine learning algorithms are able From the PMI index plot, it is clearly evident to extract complex relationships between oil price that except India and Australia, there is a drop in manufacturing activity all over the world in the countries which are under consideration, based on factor analysis.

(PMI Index) based on 12 months average, 3 months average and 1 month average of data is showing a downward trend in the past 3 months - Gold is considered as Safe Haven investment in for the manufacturing sector. Platinum, Sliver, plications as discussed in the section on inferences based on factor analysis. Russia, Poland, South Africa and Saudi Arabia had a positive PMI trend 3 months ago, but they have shown a downward trend in comparison of 3 month and 1 month data. Europe, the USA, China, have shown a consistent downward trend in their PMI Index in the past 12 months based on 12 month, 3 months and 1 month average score.

15Principal Component Analysis (PCA) - Introduction and Mathematical Formulation

Principal Component Analysis (PCA) is a technique in machine learning wherein a dataset with high dimensionality is converted into a dataset with low dimensionality, while retaining as much of the variance as possible. This is achieved by finding a new set of orthogonal axes, called principal components, along which the data varies the most. By doing this exercise, we are able to extract a small number of important features which can explain the hidden properties in our dataset. The PCA technique uses simple and intuitive mathematics from matrix algebra.

- Variance and Covariance
- Eigen Values and Eigen Factors.

Given a dataset **X** with n samples and d features, the goal of PCA is to find a new orthogonal basis \mathbf{U} such that the projected data \mathbf{Z} along these Euro_Area components has maximum variance. The first principal component is the direction along which the variance is maximized, the second principal component is orthogonal to the first and maximizes the remaining variance, and so on.

Let **X** be centered by subtracting the mean along

each feature:

$$\mathbf{X}_{\text{centered}} = \mathbf{X} - \bar{\mathbf{x}}$$

where $\bar{\mathbf{x}}$ is the mean vector.

The covariance matrix of the centered data is obtained as follows:

$$\mathbf{C} = \frac{1}{n-1} \mathbf{X}_{\text{centered}}^T \mathbf{X}_{\text{centered}}.$$

The eigenvectors \mathbf{u}_i and eigenvalues λ_i of the covariance matrix satisfy:

$$\mathbf{C}\mathbf{u}_i = \lambda_i \mathbf{u}_i,$$

where \mathbf{u}_i are the principal components and λ_i are the corresponding variances along each component.

The transformed data \mathbf{Z} along the principal components can be obtained by:

$$\mathbf{Z} = \mathbf{X}_{\mathrm{centered}} \mathbf{U},$$

where $\mathbf{U} = [\mathbf{u}_1, \mathbf{u}_2, \dots, \mathbf{u}_k]$ for k principal components.

16**Dimensionality Reduction**

To reduce the dimensionality of the data while preserving most of the variance, we can retain the top kprincipal components that correspond to the largest eigenvalues. The reduced dataset is given by:

$$\mathbf{X}_{\text{reduced}} = \mathbf{Z}[:, 1:k]\mathbf{U}^{T}[:, 1:k] + \bar{\mathbf{x}},$$

where $\mathbf{Z}[:, 1:k]$ contains the first k columns of \mathbf{Z} and $\mathbf{U}^{T}[:, 1:k]$ contains the first k columns of \mathbf{U}^{T} . Based on the ACF and PACF plots, we can choose the PDQ values as follows:

- P (Auto-Regressive Order): The lag value where the PACF cuts off.
- D (Differencing Order): The order of differencing needed to make the time series stationary.
- where the ACF cuts off.

Figure 13: Overlapping ACF and PACF plots

Based on ACF and PACF, In this case, the chosen values are P=1, D=1, and Q=2.

Results and Discussion 17

SARIMAX (Seasonal Autoregressive Integrated Moving Average with Exogenous Variables) is a time series model that incorporates both autoregressive and moving average components, as well • Q (Moving Average Order): The lag value as exogenous variables. It is widely used for forecasting and modeling time series data.

> SARIMAX Results on our dataset are depicted in Figure 15 and explained in detail. - Dep. Variable: crude brent dependent variable (exogenous time series) used in the model.

> - Model: ARIMA (1,1,2), based on the ACF PACF (p,d,q) model presented earlier in the PCA Analysis.

> - Date: The date and time when the model was fitted.

> - Sample: The range of data used for model fitting (e.g., "1970-01-01 01:00:00" to "2023-07-01 01:00:00").

- AIC (Akaike Information Criterion): A measure of the model's goodness of fit, accounting for both model complexity and fit quality. Lower AIC indicates a better model fit.

- BIC (Bayesian Information Criterion): Similar to AIC, but penalizes model complexity more heavily. It is used to compare different models, with lower values being preferred.

- Log-Likelihood: The logarithm of the likelihood Figure 17: Explained Variance vs. Number of Comfunction, which measures how well the model explains the observed data.

- LLR p-value: The p-value associated with the 18likelihood ratio test, comparing the current model to the null model. A low p-value indicates that the current model is better.

- Scale: The estimated scale parameter, which is often related to the variance of the residuals.

- Ljung-Box (Q): A test for residual autocorrela- Factor Analysis (FA): FA, on the other hand,

1. Funadamental Differences:

PCA: Analyzes Variance and assumes no underlying structure in the data.

FA: Analyzes Covariance and assumes that the observed variables are influenced by latent factors(Tab Achnick and Fidell, 2013)

- PCA: Includes all the variance in the dataset, (a) Variance of each variable.
- (b) Variance common among variables
- (c) Error variance (Gorsuch 1983, Kline 2002, Tab Achnick and Fidelb, 2013)

FA: Error Variance, and the variance unique to each variable are excluded from the analysis. Only the variance in the correlation coefficient is considered.

2. PCA: No differentiation between common and unique variance but EFA does.

3. Applications:

PCA: Often used for data compression, visualization, noise reduction.

FA: Used for understanding the underlying structure of observed correlations, e.g., in psychology or social sciences.

From our analysis, two component PCA Analysis is able to explain 80 percent of variance, which is pretty good, hence, we have been able to execute the 2 component PCA Analysis on our dataset. Similarly, 12 components are able to account for 95 percent of the explained variance. Hence, we can see that out of 50 variables, we have done data reduction to 2 components by performing PCA Analysis on the dataset. Similarly with Factor Analysis we were able to separate top 5 features based on the different machine learning algorithms. However, it is recommended to do both the analysis, in these turbulent and uncertain times, requiring more indepth reasoning in our decision making and to prevent any problems arising in the analysis due to hidden correlation and multicollinearity.

20 Conclusion

The analysis of the impact of the Russia-Ukraine conflict on Brent Crude commodity pricing using Worldbank Time Series data reveals a complex relationship among the factors influencing the fluctuations in Brent Crude prices. The ongoing war has disrupted global supply chains, causing production delays and market uncertainty. This has led to a ripple effect on the economies of major oilproducing and consuming countries.

Through a comprehensive approach, while marrying traditional time series analysis techniques such as AutoCorrelation Function (ACF), Partial AutoCorrelation Function (PACF), Seasonal Autoregressive Integrated Moving Average (SARIMA), Run Sequence Plot, and Exponential Smoothing State Space (ETS) with advanced machine learning algorithms like Random Forest, Extra Tree, Gradient Boosting, K-Nearest Neighbor, and Decision Tree, we have identified the key drivers of Brent Crude prices.

Notably, factors such as declining industrial demand for silver, disruption in vehicle production, weak demand for copper from China, and lower In essence, the research study not only sheds steel consumption have contributed to the observed light on the multifaceted nature of the Russiachanges in Brent Crude prices. These factors un- Ukraine conflict's influence on Brent Crude pricing derline the intricate relationship between commodi- but also underscores the significance of integrating ties and energy resources. The decline in industrial various analytical tools and methodologies to demand for silver speaks to the broader Industrial gain a comprehensive perspective on the intricate slowdown which has been shown in a plot of PMI's forces driving commodity price fluctuations in a by countries, this decline in demand has disrupted rapidly changing world. This analysis emphasizes various sectors and subsequently affected crude oil the need for a multidimensional approach that consumption.

Furthermore, our analysis showcases the significance of multivariate modeling techniques, including Principal Component Analysis (PCA) and Factor Analysis, in understanding the intricate relationships between different commodities and their collective impact on Brent Crude prices. These methodologies have allowed us to extract 21 crucial insights from a complex set of latencies in the interconnected variables.

As the global economic landscape continues to evolve, diplomatic negotiations, supply chain disruptions, and shifts in global trade dynamics will continue to play a pivotal role in shaping commodity prices, particularly for energy resources like Brent Crude. A holistic understanding of these dynamics, supported by both time-tested statistical methods and cutting-edge machine learning approaches, is essential for accurate forecasting and informed decision-making in the realm of commodity trading and energy markets.

For Policy makers, We have also reached the root causes of the problems for decision making, with reduced computational complexity, time and costs. At the same time, we have been able to integrate multivariate time series analysis and machine learning for a holistic global approach in policy analysis and decision making. By reaching the underline cause of complex issues, for long term solutions and evidence based decision making, we can prioritize the resources, prevent policy failures, increase stakeholder engagement for more effective policies. Hence, This research can be a valuable asset in the area of public policy decision making.

For Corporate entities, by following these time tested statistics and engineering studies, we can reach strategic decisions which can be the drivers of companies bottom line and profitability, Root-cause Analysis is the life and blood of engineering decision making in day to day life, from manufacturing processes, quality improvements, productivity studies and fault diagnostics. Hence, organizations can take decisions on quality, safety and productivity. Thus making the research useful for engineering and manufacturing.

considers geopolitical, economic, and industrial factors in tandem to truly grasp the complexities of Brent Crude pricing. As the global landscape continues to evolve, this holistic approach will remain vital for anticipating and responding to the ever-changing dynamics of the energy market.

22Recommendations

actions for various stakeholders:

1. and minimize disruptions to global markets. sifier, Random Forest Regressor, Adaboost Regres-Explore diplomatic solutions to the conflict and sor, Decision Tree Regressor have been used on

2. European nations: Diversify energy sources to reduce reliance on Russian oil and gas imports. underlying causes. The most widely used forecast-Invest in renewable energy and promote regional ing method, even if it is not fair, is the futures price, cooperation to enhance energy security.

3. Oil-producing countries: Monitor the situation closely and adjust production levels accordingly to mitigate the impact on global oil prices. Collaborate with other oil-producing nations to stabilize the market.

4. Oil-consuming countries: Diversify energy sources and reduce dependence on fossil fuels. Promote energy efficiency measures and support the development of renewable energy technologies.

Monitor market volatility and 5.Investors: consider diversifying investment portfolios to include other commodities and industries. Stay informed about geopolitical developments and their potential impact on global markets.

recommend using machine In addition, we learning algorithms such as Extra Tree, Random Forest, Gradient Boost, KNearest Neighbor, and Decision Tree for better forecasting and analysis of Brent Crude prices. These algorithms can help identify complex relationships between oil price movements and precious metals and minerals.

Overall, it is crucial for all stakeholders to remain vigilant, adapt to changing market dynamics, and explore sustainable energy solutions to mitigate the impact of the Russia-Ukraine war on Brent Crude prices and global commodity markets.

Discussion on Importance of Forecasting Research in Commodity Pricing

The ongoing Russia-Ukraine war has had a significant impact on global commodity prices, including Brent Crude. Although, Regression Models, Futures.

Artificial Intelligence and Machine Learning have been used for several decades in forecasting the commodity pricing data, but this research has used a time series dataset from the worldbank site for

doing this analysis. The research focuses on augmented forecasting techniques on commodity pric-Based on the findings, we recommend the following ing time series data, for addition to this field of research.[30]. Machine Learning methods such as Lasso, KNN, Support Vector Regressor, MLP Re-Russia: Ensure the stability of oil supplies gressor (Neural Network), Gradient Boosting Classtrengthen trade relationships with other countries. commodity pricing time series. The analysis in this study is to discover the root cause of the fluctuation in the market prices of brent crude and the which has made huge predicition errors [30].

> Additionally, Baumeister and Kilian (2015) found that mixed forecasting combining forecasts from different models, including futures prices, resulted in more accurate reporting of the model as is found useful for the fuel price forecast.

> Similarly, Manescu and Van Robays (2017) found that forecast combination approaches improved directional accuracy and unbiasedness over futures prices. Studies have shown that combining more data in different models can improve performance.

> For example, accounting for global economic conditions, petroleum inventories, world output gap, the U.S. dollar exchange rate, and the possibility of speculation has been shown to improve oil price forecasts (Baumeister, Korobilis, and Lee 2022; Kaufmann et al. 2008; Lalonde, Zhu, and Demers 2003).

> Similarly, the inclusion of significant external regressors such as industrial production, exchange rate dynamics, commodity currencies and international metal stock indices improved the forecasting performance of some metal prices (Gong and Lin 2018; Issler, Rodrigues and Burjack 2014; Pincheira, Brown and Hardy 2019)

> Multivariate time series models also have the advantage of capturing the interactions and relationships between variables. They can account for the dynamics and dependencies among different variables, allowing for a more comprehensive understanding of the underlying factors driving commodity prices.
