1. Abstract:

- Time series forecasting has been widely used to determine the future prices of stock, and the analysis and modeling of finance time series importantly guide investors' decisions and trades.
- This work proposes an intelligent time series prediction system that uses sliding-window optimization for the purpose of predicting the stock prices.
- The system has a graphical user interface and functions as a stand-alone application.
- The proposed model is a promising predictive technique for highly non-linear time series, whose patterns are difficult to capture by traditional models.

<u>2. Introduction:</u>

- Stock market prediction has been an active area of research for a long time. The Efficient Market Hypothesis (EMH) states that stock market prices are largely driven by new information and follow a random walk pattern.
- In this project, we test a hypothesis based on the premise of behave economics, that the emotions and moods of individuals affect their decision making process, thus, leading to a direct correlation between public sentiment and market sentiment.
- Financial markets are highly volatile and generate huge amounts of data daily.
- It is the most popular financial market instrument and its value changes quickly.
- Stock prices are predicted to determine the future value of companies' stock or other financial instruments that are marketed on financial exchanges.
- However, the stock market is influenced by many factors such as political events, economic conditions and traders' expectation.

What is Machine Learning:

- Machine Learning is the field of study that gives computers the ability to learn without being explicitly programmed.
- \succ More formally, it can defined as,
 - A computer program is said to learn from experience E with respect to some class of tasks T and performance measure P, if its performance at tasks in T, as measured by P, improves with experience E.
 - o Example: playing checkers.

E = the experience of playing many games of checkers

T = the task of playing checkers.

P = the probability that the program will win the next game.

What is Deep Learning

- Deep Learning is an Artificial Intelligence function that imitates the working of the human brain in processing data and creating patterns for use in decision making.
- Deep Learning is a subset of Machine Learning in Artificial Intelligence that has networks capable of learning unsupervised from data i.e., unstructured or unlabeled.
- It is also known as Deep Neural Network or Deep Neural Learning that can be used in LSTM technique to analyze the raw data and to plot predicted result.

LSTM:

- Long Short Term Memory
- LSTM units or blocks are part of a recurrent neural network in deep learning.
- These artificial intelligence programs to more effectively imitate human thought.

3.EXISTING METHOD:

- Time series forecasting consists of a research area designed to solve various problems, mainly in the financial area.
- Support vector regression (SVR), a variant of the SVM, is typically used to solve nonlinear regression problems by constructing the input-output mapping function.
- Long Short Term Memory(LSTM) units or blocks are part of a recurrent neural network in deep learning.
- The Firefly Algorithm (FA), which is a nature-inspired met heuristic method, has recently performed extremely well in solving various optimization problems.

Disadvantages:

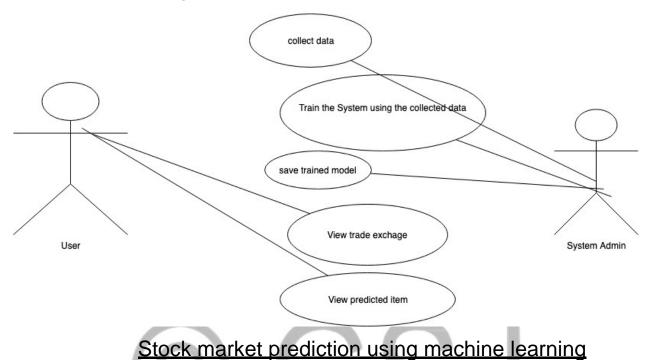

- The existing system focuses on the stock price market in Taiwan, but does not generalize for other markets worldwide.
- > The system does not allow the import of raw data directly
- The existing system cannot be used to analyze multi-variate time series.
- Lastly, the system does not have a user-interface which can be distributed as a web app to users for personal use.

4.Proposed System:

- To generalize the application of the existing system, our work uses the system to estimate other stocks in similar emerging markets and mature markets.
- The system can be extended to analyze multivariate time series data and import raw dataset directly.
- Profit can be maximized even when the corporate stock market is has lower value.
- The development of a web-based application has been considered to improve the user-friendliness and usability of the expert system.

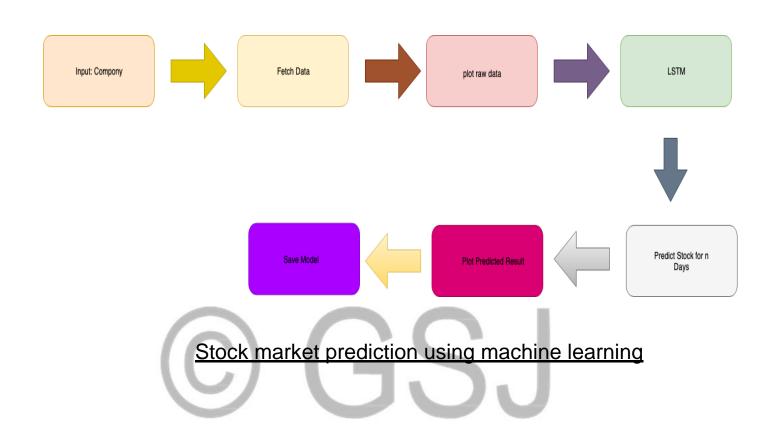

5.System Design:

Use case diagram:

- Data is initially collected from online sources or the stock exchange.
- \succ The data is then used to train the system.
- Trained model is saved.
- User view the trained exchange and stock of companies.
- \succ Using the model, closing prices are predicted.

Data flow diagram:

6. Implementation:

6.1 program/Algorithm:

import pandas as pd
import numpy as np
from keras.models import Sequential
from keras.layers import Dense, Dropout, LSTM

#to plot within notebook import matplotlib.pyplot as plt

GSJ

#setting figure size
from matplotlib.pylab import rcParams
rcParams['figure.figsize'] = 20,10

#for normalizing data

from sklearn.preprocessing import MinMaxScaler

#scaler = MinMaxScaler(feature_range=(0, 1))

#read the file

df = pd.read_csv('project.csv')

data = df.sort_index(ascending = True,axis=0)

new_data=pd.DataFrame(index=range(0,len(df)),columns=['Date','Close'])

for i in range(0,len(data)):

new_data['Date'][i] = data['Date'][i]

new_data['Close'][i] = data['Close'][i]

new_data.index = new_data.Date

new_data.drop('Date', axis=1, inplace=True)

#creating train and test sets

dataset = new_data.values

train = dataset[0:987,:]

#converting dataset into x_train and y_train
scaler=MinMaxScaler(feature_range=(0,1))
scaled_data = scaler.fit_transform(dataset)

x_train, y_train = [], []

for i in range(60,len(train)):

x_train.append(scaled_data[i-60:i,0])

y_train.append(scaled_data[i,0])

x_train, y_train = np.array(x_train), np.array(y_train)

5.

x_train= np.reshape(x_train, (x_train.shape[0],x_train.shape[1],1))

```
# create and fit the LSTM network
model = Sequential()
model.add(LSTM(units=50,
return_sequences=True, input_shape=(x_train.shape[1],1)))
model.add(LSTM(units=50))
model.add(Dense(1))
```

model.compile(loss='mean_squared_error', optimizer='adam')
model.fit(x_train, y_train, epochs=1, batch_size=1, verbose=2)

#predicting 246 values, using past 60 from the train data

inputs = new_data[len(new_data) - len(valid) - 60:].values

inputs = inputs.reshape(-1,1)

```
inputs = scaler.transform(inputs)
```

```
X_{test} = []
```

```
for i inrange(60,inputs.shape[0]):
```

```
X_test.append(inputs[i-60:i,0])
```

```
X_test = np.array(X_test)
```

```
X\_test = np.reshape(X\_test, (X\_test.shape[0], X\_test.shape[1], 1))
```

```
closing_price = model.predict(X_test)
```

```
closing_price = scaler.inverse_transform(closing_price)
```

rms=np.sqrt(np.mean(np.power((valid-closing_price),2)))

print(rms)

#for plotting

train = new_data[:987]

valid = new_data[987:]

valid['Predictions'] = closing_price

plt.plot(train['Close'])

plt.plot(valid[['Close', 'Predictions']])

Performance via Graph:

- > In this graph blue lines are representing the "Training Data".
- Green lines representing the "Actual Stock" these are taken from last 246 rows from our data set file (project.csv).
- Yellow lines in the Graph represent the "predicted Future Stock".
- In this we got Accuracy of 96.8 %.

8.Future Enhancement

- The limitation of the proposed system is its computational speed, especially with respect to sliding-window validation as the computational cost increases with the number of forward day predictions.
- The proposed model does not predict well for sudden changes in the trend of stock data.
- This occurs due to external factors and real-world changes affecting the stock market.
- We can overcome this by implementing Sentiment Analysis and Neural Networks to enhance the proposed model.
- We can modify the same system to an online-learning system that adapts in real-time.

9.Conclusion:

- Thus, as we can see above in our proposed method, we train the data using existing stock dataset that is available. We use this data to predict and forecast the stock price of ndays into the future.
- The average performance of the model decreases with increase in number of days, due to unpredictable changes in trend.
- The current system can update its training set as each day passes so as to detect newer trends and behave like an online-learning system that predicts stock in real-time.
