paulokayim@unical.edu.ng   idagr8@gmail.com

Abstract

Recent developments have witnessed increased activities in the mobile communication, be it the evolution of mobile devices, mobile applications or mobile based business solutions. This has brought about transformation of our world into a digital world. One of such mobile applications is the Incident Reporting Application (I.R.A). The incident reporting application assists with the incident management process with regard to work-related injuries at construction sites, schools or practically anywhere you or your employer work. This digital application enables you to capture right from your mobile device specifics including: the injured person, witness information, weapons used, threats, suspect and police details and more. This research work was carried out to design and implement an incident reporting application for android phones. The following programming languages were used for the design of this application CSS, JavaScript, Bootstrap, jQuery, Cordova, MySQLi while the Html text editor was used to input the programs. Two applications were developed, one for the android phone and one for computer. The application is installed on an android phone where an eyewitness of an incident uses it to record and report to the appropriate authority. The one installed on computer is for the administrator to receive reports from eyewitnesses. The exact location and scene of incident is automatically uploaded to the administrator. This application is very important because it helps to curtail deaths that occur in our schools, workplaces, highways and other places where accidents take place.

Keywords- android, bootstrap, cordova, javascript, mysqli

INTRODUCTION

The change brought by open platform technologies such as Symbian operating system and Java technologies has opened up a significant business opportunity for anyone to develop application softwares [1]. Incident reporting is very crucial in our society today owing to the multiple accidents occurrence on our highways, schools and workplaces. Reports have it that many lives lost during such scenarios are mainly due to late reporting to the relevant authority. Most times, some eyewitnesses find it difficult to describe the location of the incident and this further leaves the incident management agencies in a confused state due to inability to navigate to the scene of the accident. Google released Android which is an open-source mobile phone operating systemwith Linux-based platform [2].

This research paper "design and implementation of an incident reporting application for android phones" was designed using so many programming languages. This application enables eyewitnesses to report cases of accidents from workplaces, schools and highways by taking snapshots of it and reporting it to the nearest relevant authority for further action to be taken [3]. The eyewitness must ensure that his/her global positioning system (GPS) is activated so that the exact location and time can be sent. The relevant authority will receive a notification about the accident via its web console or administrator and teams will eventually be dispatched as soon as possible [4].

RELATED WORKS
Mobile application development is becoming more challenging with diverse platforms and their software development kits [5]. Contributions of

other research works provided useful information for successful development and implementation of the Incident reporting application. A very handful of them were documented for research purposes. They include the following:

[6] worked on incident reporting application and opines that the incident reporting application "keep records and tracks injury accidents, Track incidents by location, type, employee, date range and more, filter reports by type and location, Automatic incident creations for related programs, upload photos and supporting documents for detailed reference and Generate instant notifications to key personnel's email or mobile device".

[7] worked on: "incident reporting application for iTunes" and said that "The mobile app lets an authorized user create an Incident Report from their iPhone, iPad, or iPod touch. You can do everything that you would do with a paper form, including getting signatures. When you're done, print your report directly from the mobile device to any wireless or AirPrint-compatible printer or, authorized users can access the completed report online from the Web Console".

Though majority of research works carried out on mobile incident reporting application focuses on apples' phones without a consideration of android phones which seems to have taken control of mobile phones market especially in Nigeria because it's cost-effective and availability of its applications on google play store. It is on this premise that design and implementation of incident reporting application for android phones aim to provide solutions to in the subsequent chapters of the research.

DESIGN METHODOLOGY

This is an android app created using the following technologies, html, css, JavaScript, Bootstrap, jQuery, Cordova, MySQLi etc. This is a hybrid application due to its nature and the properties. Briefly, we will examine what hybrid applications are and their advantages:

Hybrid applications

A hybrid application is a software application that combines elements of both native and web applications [8]. This allows it not only to be accessible on different platforms, but also to be able to get the most out of each of those platforms' capabilities. Hybrid apps are wrapped inside a native application-platform. Thus we say that the design and layouts of these apps are constructed using the native app methodology while its content is web-based. The combination of both technologies result in a powerful app being developed that access all the features of a native app such as "accessing data from other apps, offline working, and ability to be downloaded from an app."

Advantages of hybrid applications

1.Enhanced UX/UI

Hybrid application development offers a consistent and flawless user experience acros Ios, android platforms [7].

2. Offline working

Due to their method of development, they can be operated in offline mode. This allows users to create and save data even when not connected to the internet.

3. Easy scaling

Hybrid applications can be programmed to fit into a wide range of different android and non-android devices and this can be accommodated in both operating systems (OS). It thus gives us an idea of the fact that codes ranging from simple to complex can be programmed based on the given OS and as a result, application developers don't need to start writing codes from scratch rather editing the previous codes to suite their choice of device and application. Devices that allow hybrid applications that to run without error are "android, blackberry, windows phone and apples operating system (iOS) devices".

FRAMEWORK USED

1. Cordova / phonegap

Cordova scaffolds a web view using the phone's native browser and encapsulate them within a mobile container. It contains a wide range of APIs and plugins that allow developers to interface with default phone functionality using JavaScript.

jQuery

The jQuery language is "fast, small, and feature-rich JavaScript library. It automates programs like HTML document traversal and manipulation, event handling, animation, and Ajax much simpler with an easy-to-use API that works across a multitude of browsers".

Bootstrap

This refers to a "free and open-source front-end web framework for designing websites and web applications". It comprises of the basic web content development and design layouts languages–"based design templates for typography, forms, buttons, navigation and other interface components, as well as optional JavaScript extension".

The application concerns itself with front-end development only unlike others.

UI/UX design

The UI was created using Photoshop and implemented using the following technology, Html5 (hypertext mark-up language) was used for the basic mark up. CSS (cascading style sheet) was used for styling the applications which include the colour scheme and structure. Bootstrap and jQuery were also used to extend the html functionality and improve user experience. JavaScript was to optimize client side interactions with form, event and overall DOM manipulation.

Application programming interface (API)

GoogleMap API: I made use of google map api to get the current map of the area which is then populated with my custom markers for the reports cases.

Geolocation API: Html5 geolocation api was also used to get the user's current location while the report is been made. This accesses the user GPS

application and provides the app with the user's longitude and latitude which aid in getting the exact location of the incident.

Camera API: cordova camera api was also used to access the device camera which enable the reporter to capture moment of the incident with their phones.

Rest API: I also created my own RESTful Api to enable the app communicate with the cloud backend to store and retrieve data when needed.

Backend

The backend was created using a progr Figure 1: Application architectural design MySQLi (the improve version of MySQL) to enable the app make request or query to the database. The Database holds all the information about the report and has the following table structure:

"Format: create table if not exists `report` (`id` int(11) not null auto_increment, `name` varchar(255) not null, `title` varchar(255) not null,
 `description` text not null,
 `lat` varchar(255) not null,
 `lon` varchar(255) not null,
 `image` varchar(255) not null,
 primary key (`id`)
) engine=innodb default charset=latin1 auto_increment=86 ;"

Admin panel
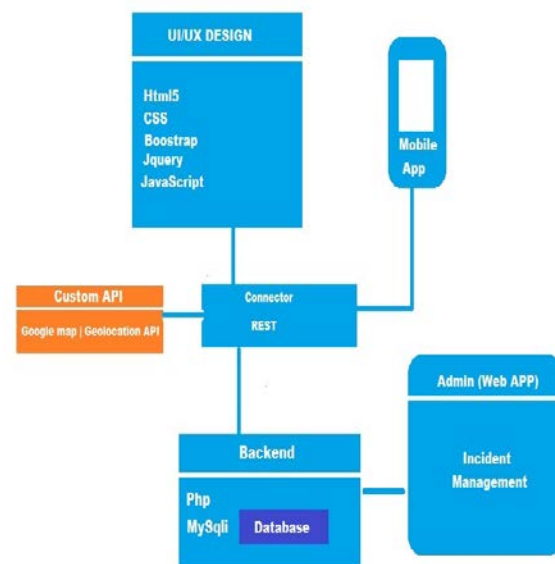

The admin panel is a web app which provides the management with report of the entire incident made, analysis of report, reports pending and details of reports, such as, the current location of the incident and other information that may be useful to help track the reported case.

System Requirements

- Android 2.0 and above
- Camera-enable
- GPS-enable
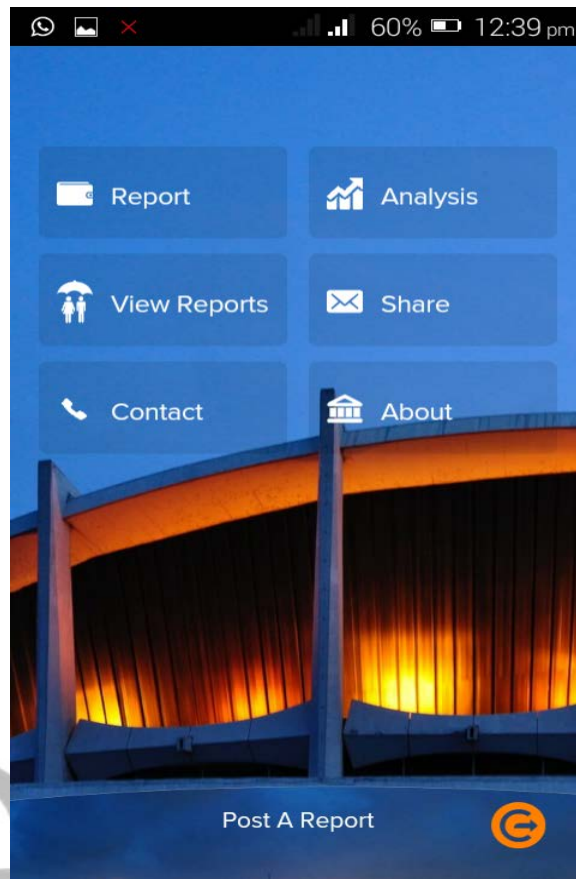

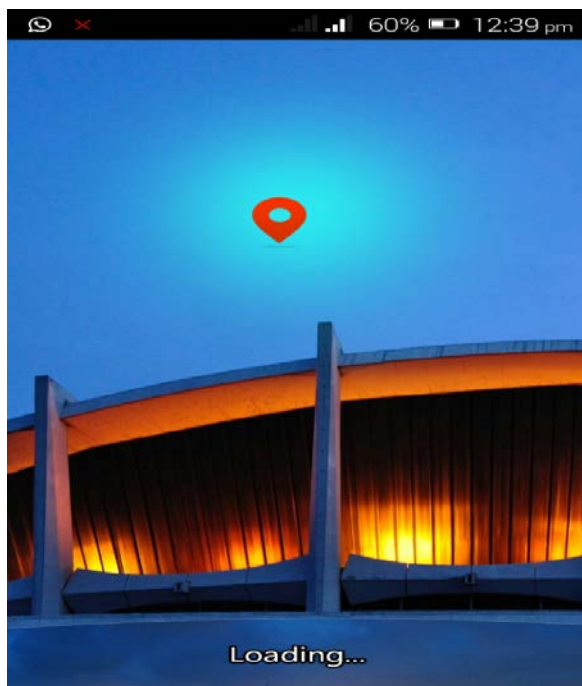

Figure 5: Launching of the incident reporting application
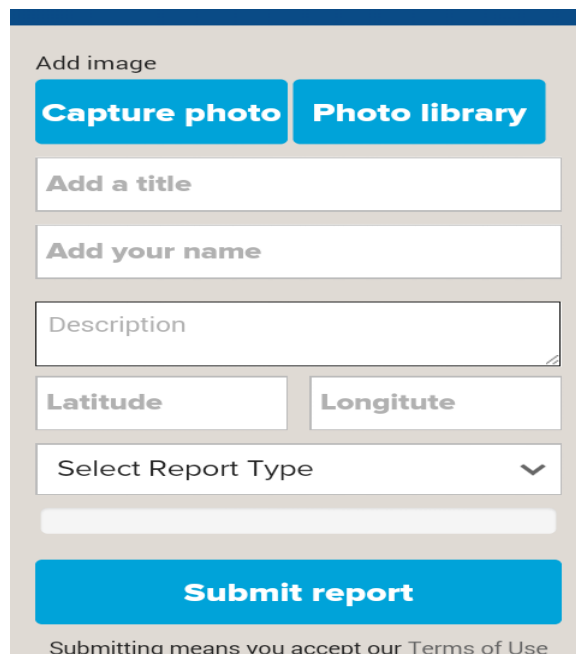

This research work was carried out to help emergency managements and governments to reduce casualties in case of incidents occurrence in our schools, workplaces, roads and other public places. Incident reporting application is a timely breakthrough in mobile telecommunication as its impact constitutes great deal in our society.

The programming languages used for the design of the application are readily available in the internet. One of the striking features of this application is its ability to upload automatically the coordinates (latitude and longitude) to the administrator.

The administrator immediately gets a notification of the message and can trace the actual location of the incident, the exact street, the satellite view of the place and even calculate the distance it will take him to get to the place where the incident took place.

RECOMMENDATION

Implementation of an incident reporting application for Android Phones is a virgin research field as this is the pioneer research carried out on this work. I is against this back drop that future research work is being encouraged to be carried out so as to improve the current work. Also, since the source codes will be in public domain, it will be much easier for Web programmers and Web application developers to dive into and upgrade the current application.

This work is also recommended to emergency response centers for integration of it into their modus operandi to help reduce death rates in cases of incident occurrences.
